Professor Lawrence F. Katz
Editor, *The Quarterly Journal of Economics*

Dear Professor Katz,

When you declined my paper "Housing First or Treatment First?" (MS 45355), you did not see a large enough advance or a sufficiently compelling empirical base. I have since written a different paper, "Children First, Housing Later," that addresses both, and I would like to ask whether you would consider it as a new submission. Its question, its model, its experiments and its conclusion are new: the model now includes children and the externalities a parent's drug use imposes on them. Even what the two share, the explanation for why drug use concentrates among the poor, is now shown clearly to be the result of uninsurable risk, not of preferences that differ systematically with income, using a simple, stripped-down two-period model that isolates the mechanism.

The advance. The first paper asked whether conditioning housing assistance on sobriety reduces addiction and homelessness through moral hazard. It found that, with the number of vouchers fixed, conditionality lowers addiction but raises homelessness and lowers welfare; Treatment First came out ahead only with universal vouchers and with a cost of premature death to survivors (loss of consortium) added to welfare by hand. The new paper drops that term and shows that moral hazard does not decide the question: without effects on children, a newborn is worse off under Treatment First, by 1.09 percent of lifetime consumption, even though drug use falls. The answer turns on the children. A parent's drug use costs the child consumption and housing at home, and earnings as an adult, and the parent counts these only in part. Within the existing rationed programme, Treatment First cuts drug use by 21 percent and homelessness by 11 percent, and raises a newborn's welfare by 2.57 percent, three quarters of it an externality the parent does not count. The model reproduces many micro findings of randomised controlled trials, including that households with a disorder lose from the condition. What reverses the verdict is what trials cannot observe: the households the condition deters from using, the vouchers its savings fund, and the children.

The empirical base. Each mechanism that drives the answer is now pinned to direct evidence. The earnings penalty a child bears from a parent's disorder is set to the natural-experiment estimate of Nilsson (2017), the deterrence of the drug test to the US military's random testing (Mehay and Pacula, 1999), and the effect of housing on recovery to the randomised trial of Milby et al. (2005). Without being targeted, the model reproduces that trial's effect of making housing conditional on abstinence (1.40 against 1.26) and the effect of Housing First on the three-year mortality of homeless veterans with mental illness (3.6 against 4.6 percentage points; Costantini, 2025).

The model and the transition. Its other new elements are serious mental illness, a choice of treatment, a drug price that clears its market (it was held fixed in the first paper), and a budget balanced through the rationing of vouchers rather than through taxes. In the transition, which covers every cohort alive at the reform and clears the drug price and the budget every period, homelessness and childhood homelessness never rise, and children born at the reform gain 1.45 percent. Alternative transitions, with households unable to stop using, an announced screen or a temporary exemption in treatment, show how the first years depend on the reform's design.

The question is current: in July 2025 an executive order directed federal agencies to end support for Housing First. Both papers are attached to this email. I would be grateful for your guidance.

Sincerely,

Shahar Rotberg
